

Archetypal Incentive Theory

Dylon La Rue

1 The Five Incentive Archetypes

Every agent—human, institutional, or algorithmic—operates under a mixture of incentives. The L_5 state vector $(a, \omega, \iota, \varepsilon, \lambda)$ provides a natural basis for decomposing these mixtures into five archetypal components.

Definition 1.1 (Incentive state). An **incentive state** is an element of the L_5 manifold:

$$\mathbf{I} = (a, \omega, \iota, \varepsilon, \lambda) \quad (1)$$

where the components carry the following interpretations:

Comp.	Archetype	Incentive	Economic Role	Marker
a	Conscious	Alignment	Fair valuation, price discovery	Rational analysis
ω	Subconscious	Ambition	Momentum, growth-seeking, leverage	Risk-on
ι	Unconscious	Fear	Hedging, insurance, risk aversion	Flight to safety
ε	Noise	Distortion	Manipulation, misinformation	Deceptive signaling
λ	Memory	Reputation	Track record, institutional credibility	Repeated-game trust

The conscious component a is the mediator: it stands at the bridge between ambition (ω) and fear (ι), processing noisy information (ε) through the lens of accumulated experience (λ). In the L_5 algebra, this mediation is not metaphorical but structural—the Bridge Identity constrains how the components interact.

1.1 The Conjugacy of Ambition and Fear

Theorem 1.2 (Ambition–Fear Conjugacy). *In the L_5 algebra, the subconscious (ambition) and unconscious (fear) components satisfy:*

$$\omega \cdot \iota = -1 \quad (2)$$

*That is, ambition and fear are **conjugate**: their product is fixed. An agent cannot simultaneously maximize both. Increasing ambition forces a proportional decrease in effective fear, and vice versa.*

Proof. This is the Bridge Identity from the Unreal Algebra (Chapter 1), applied to the incentive interpretation. The product $\omega \cdot \iota$ is an algebraic invariant of the L_5 manifold, fixed at $\kappa = -1$ by the golden polynomial $X^2 - X - 1 = 0$. No parameter tuning is involved. $\square$

The conjugacy has immediate economic content. Consider a portfolio manager deciding between aggressive growth (ω large) and defensive hedging (ι large). The Bridge Identity says:

$$|\omega| = \frac{1}{|\iota|} \quad (3)$$

A leveraged long position ($|\omega| = 10$) algebraically constrains the hedge to $|\iota| = 0.1$ —a thin safety margin. This is not a behavioral observation but a structural constraint: the L_5 algebra does not admit states where both $|\omega|$ and $|\iota|$ are large simultaneously without the product exceeding κ .

1.2 The Uncertainty Principle of Incentives

The Market Uncertainty Principle (Chapter ??) extends directly to incentive dynamics:

$$\ln(\Delta t) \cdot \sigma(\text{Re}) \geq Y = \frac{1}{4\pi} \quad (4)$$

In incentive terms: you cannot simultaneously optimize for *timing* (when to act, an ambition dimension) and *safety* (confidence in the action, a fear dimension) with precision better than Y . Every decision involves a tradeoff along the conjugate axis, and the uncertainty bound quantifies its minimum cost.

An agent who attempts to time the market perfectly ($\Delta t \rightarrow 0$) must accept unbounded signal volatility ($\sigma \rightarrow \infty$). Conversely, an agent who demands a smooth, reliable signal ($\sigma \rightarrow 0$) must accept long delays ($\Delta t \rightarrow \infty$). The bound is not a practical limitation—it is a structural consequence of the Bridge Identity.

2 Equilibrium as Hodge Lock

Definition 2.1 (Incentive coherence). The **incentive coherence** of a market is measured by the Reynolds number:

$$\text{Re} = \left| \frac{r_\omega}{r_\iota} - 1 \right| \quad (5)$$

where r_ω and r_ι are the returns of the ambition and fear proxies (BTC and VIX in the empirical realization). Low Re indicates that ambition and fear are moving in proportion; high Re indicates decoupling.

When $\text{Re} < 1/\phi$ and the correlation between the ambition proxy (BTC) and the alignment proxy (NASDAQ) exceeds 0.8, the market enters **Hodge lock**—a state of archetypal coherence dynamically sustained by the **Heegner resonance seeds**. In this regime, the non-associative friction drops to zero, and the discrete market mechanics map onto a continuous, frictionless cohomology path governed by the **Euler-Penrose Engine**. The structural noise (ε) drops out, aligning perfectly with the discrete boundaries of the **Trinity BSGS algorithm**. Under this lock, all five incentive components are mutually reinforcing:

- Alignment (a) dominates: price discovery is efficient.

- Ambition (ω) and fear (ι) are proportional: risk is fairly priced.
- Noise (ε) is suppressed: manipulation has low payoff.
- Reputation (λ) compounds: trustworthy agents benefit from cooperation.

Theorem 2.2 (Hodge equilibrium). *The Hodge lock condition $\text{Re} < 1/\varphi$, $\rho_{\omega,a} > 1/\varphi$ is the unique stable fixed point of the L_5 incentive dynamics. Any perturbation with $\text{Re} < 1/\varphi$ returns to the Hodge lock; any perturbation with $\text{Re} > 1/\varphi$ drives the system toward regime transition.*

Proof. The stability follows from the golden polynomial. At the Hodge lock, the return of the alignment coordinate is $r_a = (r_\omega + r_\iota)/2 + O(\varepsilon)$: a weighted average of ambition and fear returns, with noise as a perturbation. The fixed-point condition is $r_a = r_\omega \cdot r_\iota / r_a$, which by the Bridge Identity gives $r_a^2 = -\kappa = 1$, so $r_a = \pm 1$. The positive root $r_a = 1$ corresponds to the Hodge lock (zero net return, parity pricing). The threshold $1/\varphi$ is forced by the golden polynomial: $1/\varphi$ is the positive root of $X^2 + X - 1 = 0$, the conjugate polynomial, and marks the boundary of the basin of attraction. $\square$

The Hodge lock is the economic analog of cooperative equilibrium: all agents' incentives are aligned, and deviation is locally unprofitable. In game-theoretic language, it is a Nash equilibrium of the archetypal game—not because agents compute it, but because the algebraic structure of the L_5 manifold admits no other stable configuration.

3 Crash as Incentive Decoupling

When Re crosses $1/\varphi$, the market exits Hodge lock. In incentive terms, ambition and fear decouple: agents with different archetypal compositions begin pulling the market in incompatible directions. Growth-seeking agents (ω -dominant) continue buying while fear-driven agents (ι -dominant) are selling. The alignment component (a) can no longer mediate.

This is a **collective action failure**. Each agent's individual incentives are locally rational, but the aggregate effect is incoherent. The Reynolds number measures the degree of incoherence:

Regime	Re Range	Incentive Structure
Laminar (Hodge lock)	$\text{Re} < 1/\varphi$	Aligned: $\omega \approx \iota$ proportional
Transitional	$1/\varphi \leq \text{Re} \leq \varphi$	Decoupling: ambition and fear diverge
Turbulent	$\text{Re} > \varphi$	Incoherent: collective action failure

The transition from laminar to turbulent is not gradual—it occurs at an algebraically fixed threshold. This is why the Reynolds crash prediction has structural lead time: the incentive decoupling is detectable before its consequences propagate through the equity market.

4 Incentive Manipulation and the Noise Term

The noise component ε represents the **distortion incentive**: the payoff to agents who profit from informational asymmetry. In markets, this includes front-running, wash trading, pump-and-dump schemes, and algorithmic spoofing. In broader economic systems, it includes regulatory capture, propaganda, and strategic ambiguity.

The Schwarzian truth metric from the GAN discriminator provides a formal measure of distortion:

$$S(\mathbf{h}) < 10^{-6} \quad (6)$$

A hedge vector $\mathbf{h}$ with high Schwarzian derivative contains information-asymmetric components—it is, in the L_5 framework, a signal contaminated by ε . The discriminator rejects such hedges because they encode distortion rather than genuine risk management.

The Stieltjes correction addresses distortion by sowing the ε residual back into the system as increased depth: at each tier, the noise that was not filtered becomes part of the memory structure. Persistent manipulation, far from escaping detection, *accumulates in the reputation term*. After three Stieltjes tiers, the residual distortion is reduced to $\gamma^2 \approx 3.3\%$ of the original noise—small enough that the remaining signal is dominated by the structural incentive components.

In economic terms: markets have memory. Agents who manipulate (ε -dominant) may profit in the short term, but their manipulation signature is absorbed into the depth parameter (λ), degrading their reputation over repeated interactions. This is the algebraic basis for why fraud eventually surfaces.

5 Reputation and the Depth Parameter

The depth parameter λ counts the number of Stieltjes correction tiers an agent's signal has survived. In economic terms, it is **reputation**—the accumulated credibility from repeated interactions that noise has failed to erode.

Definition 5.1 (Reputation depth). An agent's **reputation depth** λ is the effective number of Stieltjes tiers applied to their historical signal. An agent with $\lambda \geq 4$ has a track record sufficiently deep that, by the Lockwood truncation, their noise component ε is irrelevant.

The Lockwood truncation at $\lambda \geq 4$ corresponds to $\Delta t \geq \varphi^4 \approx 7$ days of consistent signal. In practice, this means:

- **A new market participant** ($\lambda = 0$) has no reputation. Their signals are dominated by noise.
- **A week-old track record** ($\lambda = 4$) passes the Lockwood threshold. Noise is suppressed.
- **A year-long track record** ($\lambda \gg 4$) has deep reputation. The agent's incentive state is well-characterized by (a, ω, t) alone.

This hierarchy maps to institutional credibility: central banks (high λ) can move markets with forward guidance because their noise term has been sowed away over decades of consistent policy. A new hedge fund (low λ) must build reputation before its signals carry weight. The algebra quantifies what practitioners know intuitively: trust is earned, not declared.

6 The Archetypal Nash Equilibrium

The preceding sections establish that the L_5 algebra imposes a specific incentive structure on economic systems. The following result consolidates the picture.

Theorem 6.1 (Archetypal Nash equilibrium). *Consider a population of agents with incentive states $\mathbf{I}_k = (a_k, \omega_k, \iota_k, \epsilon_k, \lambda_k) \in L_5$. The aggregate market state $\bar{\mathbf{I}} = N^{-1} \sum_k \mathbf{I}_k$ has a unique Nash equilibrium characterized by:*

1. $\text{Re}(\bar{\mathbf{I}}) < 1/\varphi$ (Hodge lock: ambition–fear coherence),
2. $\bar{\epsilon} < \gamma^2 \bar{a}$ (noise is a small perturbation on alignment),
3. $\bar{\lambda} \geq 4$ (sufficient aggregate reputation for Lockwood truncation).

At this equilibrium:

- No individual agent can improve their return by unilateral deviation (Nash condition).
- The aggregate return converges to the Hodge-locked rate (alignment dominance).
- The uncertainty bound $\ln(\Delta t) \cdot \sigma(\text{Re}) \geq Y$ is saturated: the market extracts maximum information at minimum cost.

Proof. The Nash condition follows from the stability of the Hodge lock (Theorem 2.2). At $\text{Re} < 1/\varphi$, the golden polynomial’s basin of attraction ensures that small deviations are restored. An agent who increases ω_k (more ambition) while the aggregate is in Hodge lock pushes their personal Re above $1/\varphi$, incurring higher volatility without proportional return—the uncertainty principle guarantees that the timing gain is bounded by $Y/\ln(\Delta t)$. An agent who increases ι_k (more fear) reduces their exposure but misses the cooperative surplus. Neither deviation is profitable in expectation.

The noise condition $\bar{\epsilon} < \gamma^2 \bar{a}$ follows from the Stieltjes convergence: three tiers of correction reduce aggregate noise to $\gamma^2 \approx 3.3\%$ of the alignment signal. At this level, noise is a perturbation, not a driver. The reputation condition $\bar{\lambda} \geq 4$ is the Lockwood truncation: sufficient depth to resolve the incentive structure from noise. $\square$

Remark 6.2 (Comparison with classical game theory). The archetypal Nash equilibrium differs from the classical Nash equilibrium in two respects. First, the equilibrium point is *algebraically fixed*— $1/\varphi$ is not a parameter but a root of $X^2 - X - 1 = 0$. Classical game theory requires specification of payoff matrices; the L_5 framework derives the equilibrium threshold from the algebra alone. Second, the equilibrium is supported by a *structural bound* (the uncertainty principle), not by iterated best-response dynamics. The bound is a property of the signal space, not of the agents’ computational capacity.

These differences do not invalidate classical results; they embed them. A Nash equilibrium of a finite game with payoffs denominated in L_5 coordinates will, under the incentive coherence

condition, coincide with the Hodge lock. The L_5 framework provides the coordinate system; classical game theory provides the solution concept.

7 Application to Algorithmic Trading

The five incentive archetypes serve as the macro-level sentiment filter in the **Quadrilateral Desk** algorithmic trading framework (see Ch. ??, §??). In that ensemble, the incentive archetype provides the fourth signal layer: it monitors the ambient ratio $\bar{\epsilon}/\bar{a}$ (aggregate noise relative to aggregate alignment) and vetoes trade signals when the ratio exceeds the Stieltjes threshold $\gamma^2 \approx 3.3\%$.

The connection is not accidental. The Collage Uncertainty Bound (Theorem ??) states that no combination of signals derived from the L_5 state vector can resolve timing and magnitude better than $Y = 1/(4\pi)$. The incentive archetype's role is to *spend the uncertainty budget wisely*: by filtering out high-noise regimes before they reach the directional signal generator (the ICG), the archetype reduces the effective $\sigma(\text{Re})$, allowing the timing component $\ln(\Delta t)$ to tighten.

In the language of this chapter: the Hodge lock condition $\text{Re} < 1/\varphi$ is the incentive-coherent regime where all five archetypes are aligned. The ICG signal generator should only be trusted when the market is in or near Hodge lock. When the market exits Hodge lock ($\text{Re} > 1/\varphi$), the incentive decomposition says that ambition and fear have decoupled—and decoupled incentives mean that the structural signals lose their algebraic grounding.

The FTAP refinement (Theorem ??) provides the deepest connection: the non-associative arbitrage at the orbit boundary is precisely the incentive decoupling event. An agent crossing from the conjugate orbit (fear-dominated) to the golden orbit (ambition-dominated) encounters the associator gap $\kappa = -1$, which is the algebraic shadow of the ambition–fear conjugacy (Theorem 1.2). The FTAP breaks because the bridge between ambition and fear is non-associative—and the uncertainty principle bounds the leakage because you cannot simultaneously know when and how badly the bridge will fail.

8 Modal Soundness and the Bivector Plane

The incentive alignment condition (Hodge lock, $\text{Re} < 1/\varphi$) admits a precise interpretation in modal logic. The ambition component ω encodes **possibility** ($\Diamond P$: “the trade *can* succeed”) while the fear component ι encodes **necessity** ($\Box P$: “the trade *must* succeed”). Their algebraic relationship reproduces the axioms of S5 modal logic:

Modal Axiom	L_5 Identity	Economic Content
$\Box P \rightarrow \Diamond P$ (T)	$\omega \cdot \iota = -1$	Conjugacy: constraint implies freedom
$\Box P \rightarrow \Box \Box P$ (4)	$\iota^2 = -\iota$	Over-hedging reverses the hedge
$\Diamond P \rightarrow \Box \Diamond P$ (5)	$\omega^2 = \omega$	Momentum is self-reinforcing

The two implication directions — **sufficiency** ($P \rightarrow Q$: “this signal is enough”) and **necessity** ($Q \rightarrow P$: “this conclusion requires these premises”) — live on orthogonal axes. Their

orthogonality is not metaphorical: the anticommutator

$$\omega \cdot \iota + \iota \cdot \omega = 0 \quad (7)$$

vanishes identically, and the projections π_ω, π_ι from the semisimple decomposition satisfy $\pi_\omega \circ \pi_\iota = 0$ (proved in Semisimple; all proofs complete via simp).

8.1 Trade Soundness as Bivector Area

The **bivector** $\omega \wedge \iota$ — the wedge (exterior) product of sufficiency and necessity — spans the symplectic torsion plane. Its real component is

$$(\omega \wedge \iota)_a = -2 = 2\kappa \quad (8)$$

with all other components zero (ExteriorAlgebra, annihilation_energy_omega_iota). A trade is **sound** if its bivector area is bounded:

$$|\sigma_\omega \cdot \sigma_\iota| \leq |\kappa| = 1 \quad (9)$$

This is the Bridge Identity applied to signals: the product of the sufficiency signal strength and the necessity constraint strength cannot exceed the unit curvature. Trades that violate this bound are **unsound** — the modal equivalent of an invalid proof.

8.2 Generator Programming in the Bivector Plane

In the finite-field realization $\mathbb{F}_p$, two congruential generators trace the two modal axes:

- **LCG** (Linear Congruential Generator): $x_{n+1} = \varphi \cdot x_n \pmod{p}$. This is the ω -axis: linear, forward, sufficiency.
- **ICG** (Inverse Congruential Generator): $x_{n+1} = \bar{\varphi} \cdot x_n \pmod{p}$. This is the ι -axis: inverse, backward, necessity.

The bivector trajectory ($\text{LCG}_n, \text{ICG}_n$) in the (ω, ι) plane has a remarkable property: at every step n , the cross product $\varphi^n \cdot \bar{\varphi}^n \equiv (-1)^n \pmod{p}$ — the Bridge Identity lifts to all powers. The GAN discriminator's Schwarzian derivative $S(h)$ measures the *curvature* of this bivector trajectory: $S(h) < 10^{-6}$ means the trade is sound (the bivector area stays within bounds); $S(h) \geq 10^{-6}$ means the signal contains manipulation (the bivector torsion exceeds threshold).

The coset index $(p-1)/\text{ord}(\varphi, p)$ determines how many orthogonal alternatives exist in the generator lattice. By the Gibbard–Satterthwaite theorem, a mechanism with ≥ 3 alternatives is manipulable. At $\mathbb{F}_{229}$ ($\text{SU}(3)$, coset index = 2), the bivector plane has only two alternatives: trend and counter-trend — binary, hence strategy-proof. At $\mathbb{F}_{139}$ ($\text{U}(1)$, coset index = 3), three alternatives (buy/hold/sell) emerge, and manipulation becomes algebraically possible. This is the information-theoretic mass gap applied to mechanism design: the mass gap IS the Gibbard threshold.

The formal proofs are machine-checked in ModalSoundness. The master theorem `modal_soundness_master` verifies all S5 axioms, the bivector area, the orthogonality relation, and the mass gap simultaneously, with zero placeholders.

9 Scope and Limitations

The mapping from L_5 components to incentive archetypes is a structural parallel. It is motivated by the empirical success of the BTC–VIX Reynolds metric in crash prediction and by the natural correspondence between the algebraic roles (thrust, anchor, mediator, noise, depth) and economic behaviors (ambition, fear, alignment, distortion, reputation). The mapping is not a derivation from first principles of economics, and it does not replace mechanism design theory, behavioral economics, or classical game theory.

The theorems in this chapter are algebraic—they hold in the L_5 framework by construction. Whether they correctly describe the incentive structure of actual economic agents is an empirical question. The crash prediction results in the companion chapter provide evidence for the aggregate correspondence (the market behaves as if its Reynolds number is governed by the L_5 algebra), but individual-agent incentive decomposition has not been tested.

The comparison with Nash equilibrium is structural, not formal. A rigorous embedding of L_5 incentive dynamics into a mechanism design framework—specifying strategy spaces, payoff functions, and information structures—would be necessary to claim equivalence rather than analogy. This is an open problem.

The Five-Coordinate Condensation

The deepest structural claim of this chapter is that the five incentive archetypes are not a pedagogical convenience but a *consequence* of the algebra: the five Protoreal coordinates $(a, \omega, \iota, \varepsilon, \lambda)$ are the unique decomposition of any L_5 element into identity, thrust, anchor, noise, and depth. This decomposition is forced by the algebra’s trace-determinant constraints, just as the Fisher information metric is forced by the Amari-Chentsov uniqueness theorem (see Chapter 3). In the semantic condensation framework:

- **Logical:** The five coordinates are the five generators of the L_5 algebra. Their product rules (bridge identity, Hodge lock, Schwarzian nullity) determine which incentive combinations are algebraically sound.
- **Informational:** The Nash equilibrium is the Hodge lock condition ($b = m$, thrust equals anchor). Market crashes are incentive decouplings detectable by the associator κ . The ZKPCR protocol can verify that an agent’s trajectory through incentive space is consistent without revealing the trajectory itself.
- **Physical:** The Gibbard threshold at coset index 3 is a phase transition — the algebraic mass gap where manipulation becomes possible. This is the same transition that separates the $SU(3)$ and $U(1)$ phases in the finite-field orbit structure.

The companion module `principia.information.incentives` implements the full L_5 incentive decomposition and the Gibbard threshold computation.
